Corrosion Avoidance with New Wood Preservatives

By Samuel L. Zelinka and Douglas R. Rammer

Metallic coating. Although coatings are a cost effective way of increasing the corrosion resistance of fasteners in treated wood, caution is still needed when specifying their use. The overall performance of a coated fastener is dependent on properties and thickness of the coating, the size and quantity of defects in the coating, and the adhesion between the coating and fastener. Furthermore, coatings that perform well in certain environments perform poorly in other environments. For example, zinc coatings perform better than cadmium coatings in industrial environments, while the reverse is true in marine environments (Mooney 2003). It is imperative that fasteners be tested in treated wood so that test results are not erroneously applied.

**Metallic/Galvanized Coating**

Metallic coatings, such as galvanizing (zinc plating), work by applying an envelope layer of metal that corrodes at a slower rate in a certain environment over the substrate metal that corrodes faster. It is important to stress that the lower corrosion rate of the coating gives it improved service life which is independent of its ranking on the galvanic series for the specific environment.

Metallic coatings can be further sub-divided into two categories, depending on the relative positions on the galvanic series of the coating and the substrate metal. If the coating is more anodic on the galvanic series than the substrate, the coating will corrode to the benefit of the substrate; that is, the coating galvanically protects the substrate. The advantage of these anodic coatings is that the substrate is protected from defects in the coating (such as pores and cracks) because of the galvanic protection. However, the anodic coating is only beneficial if the corrosion rate of the coating material is slower than that of the substrate. Common anodic coatings.
Barriers

Currently, there is at least one manufacturer who is marketing a barrier intended to go between treated wood and deck hangers to prevent corrosion. Similar to ceramic and organic coatings, barriers try to isolate the metal from the corrosive environment, and are only as effective as the number and type of defects they contain. Fasteners inserted through the barrier into the penetrate the barrier, and corrosion can occur in this area.

Dissimilar Metals

A condition that is sometimes overlooked is the combination of different metals; for example, using a stainless steel fastener to connect a hot-dip galvanized joist hanger to a deck. Galvanic corrosion occurs when dissimilar metals are placed in “electrical contact” in a corrosive environment, and the less noble metal corrodes at the expense of the more noble metal. Even if metals are protected by paint or another barrier, galvanic corrosion can still occur through defects in the barrier. The anodic (less noble) metal should never be coated since defects in the coating exacerbate the effect of galvanic corrosion by localizing it to a small surface area (Elliott 2003).

Conclusions

With the introduction of new wood preservatives, the concern for corrosion protection has increased. When considering alternatives to stainless steel for fasteners and connectors, the designer should understand the methods by which these alternatives work. Coatings inhibit corrosion by isolating the metal from corrosive conditions. For isolation to be successful, the barrier or coating must not be compromised, with the exception of metallic anodic coating. Finally, combining dissimilar metals can increase the corrosion rate because of galvanic action. This information is summarized in Table 1.
